ABSTRACT

Human life has changed from real-world to virtual worlds due to recent advancements in computer technology. Malware is superfluous software that is frequently used to initiate cyberattacks. Advanced packaging and obfuscation techniques are still being used by malware strains to evolve. These methods complicate the categorisation and detection of malware. To successfully battle emerging malware strains, new methods that differ from traditional systems should be used. All complicated and novel malware strains cannot be detected by machine learning (ML) techniques. The deep learning (DL) approach may be a viable way to identify every kind of malware. In this research, the Optimal Ensemble Learning Approach for Cybersecurity (AAMD-OELAC) approach for Automated Android Malware Detection is presented. The automatic categorisation and detection of Android malware is the main goal of the AAMD-OELAC approach. The AAMD-OELAC approach preprocesses data at the preliminary stage in order to do this. Three machine learning models—the Regularised Random Vector Functional Link Neural Network (RRVFLN), the Kernel Extreme Learning Machine (KELM), and the Least Square Support Vector Machine (LS-

SVM)—are used in the AAMD-OELAC technique's ensemble learning process for Android malware detection. Lastly, the three DL models' optimal parameter tuning is achieved by utilising the hunter-prey optimisation (HPO) technique, which also contributes to better malware detection outcomes. A thorough experimental investigation is carried out to demonstrate the superiority of the AAMD-OELAC approach. The simulation results demonstrated the AAMD-OELAC technique's superiority over other methods already in use.

1. INTRODUCTION

Network engineers and computer scientists are increasingly concerned about cyber security, thus finding satisfactory answers to a number of issues is necessary [1]. As a result, different malware programs and targets are well-identified and researched, as are the rapid advancements in technology and their intrinsic integration into all facets of lifestyles [2]. The malware kind that attracted the most attention in the online community is Android malware. Android is a popular operating system that leads the market for operating systems [3].

Malware invasive methods emerge for avoiding identification, as few malware

applications have more than 50 parameters that make detection a difficult one [4]. Hence, it is essential to devise techniques that deal with the continuous growth of Android malware to find it, deactivate or remove it efficiently. All these difficulties engage scholars in the area and urge them to continue more research to find malware and manage it properly [5]. Thus, researchers have developed three mechanisms to find Android malware such as dynamic, static, and hybrid analysis methods. Static analysis extracts the features that assist in identifying harmful performance for apps without a demanding actual application deployment [6]. But this kind of analysis suffered from code obfuscation methods which assist help malware author to avoid static methods. Dynamic analysis can be used for determining the malware of apps in their runtime [7]. Commonly, the static analysis feature offers the capability of locating the malware element using source code, while the dynamic analysis feature offers the capability of finding the location of malware in a runtime environment. Android developers and users can be exposed to unnecessary risks and dangers with malware [8]. This study covers malware detection methods. The detection of malware using the ML model includes Android Application Packages (APKs) for deriving an appropriate set of features. Deep learning (DL) and machine learning (ML) approaches can be used for recognizing malicious APKs [9]. Like malware detection, vulnerability detection in software code has two stages: training ML on derived attributes to find vulnerable code segments

and feature generation utilizing code analysis [10].

This paper presents an Automated Android Malware Detection using Optimal Ensemble Learning Approach for Cyber security (AAMD-OELAC) technique. The AAMDOELAC technique performs data preprocessing at the preliminary stage. For the Android malware detection process, the AAMD-OELAC technique follows an ensemble learning process using three ML models, namely Least Square Support Vector Machine (LS-SVM), kernel extreme learning machine (KELM), and Regularized random vector functional link neural network (RRVFLN). Finally, the hunter-prey optimization (HPO) algorithm is exploited for the optimal parameter tuning of the three DL models, and it helps accomplish improved malware detection results. To indicate the supremacy of the AAMD-OELAC approach, a comprehensive experimental analysis is carried out. In short, the key contributions are listed as follows.

- An intelligent AAMD-OELAC technique comprising data preprocessing, ensemble learning, and HPO-based hyper parameter tuning is presented for Android malware detection. To the best of our knowledge, the AAMD-OELAC technique never existed in the literature.

- Perform ensemble learning-based classification process comprising LS-SVM, KELM, and RRVFLN models for Android malware detection.

- The combination of the HPO algorithm and ensemble learning process improves the detection accuracy of Android

malware. By utilizing multiple classifiers and optimization strategies, the model can effectively identify malicious patterns and behaviors in Android applications.

2. LITERATURE SURVEY

“Adversarial superiority in Android malware detection: Lessons from reinforcement learning based evasion attacks and defenses,”

Today, android smartphones are being used by billions of users and thus have become a lucrative target of malware designers. Therefore being one step ahead in this zero-sum game of malware detection between the anti-malware community and malware developers is more of a necessity than a desire. This work focuses on a proactive adversary-aware framework to develop adversarially superior android malware detection models. We first investigate the adversarial robustness of thirty-six distinct malware detection models constructed using two static features (permission and intent) and eighteen classification algorithms. We designed two Targeted Type-II Evasion Attacks (*TRPO-MalEAttack* and *PPO-MalEAttack*) based on reinforcement learning to exploit vulnerabilities in the above malware detection models. The attacks aim to add minimum perturbations in each malware application and convert it into an adversarial application that can fool the malware detection models. The *TRPO-MalEAttack* achieves an average fooling rate of 95.75% (with 2.02 mean perturbations), reducing the average accuracy from 86.01% to 49.11% in thirty-six malware detection models. On the other

hand, The *PPO-MalEAttack* achieves a higher average fooling rate of 96.87% (with 2.08 mean perturbations), reducing the average accuracy from 86.01% to 48.65% in the same thirty-six detection models. We also develop a list of the *TEN* most vulnerable android permissions and intents that an adversary can use to generate more adversarial applications. Later, we propose a defense strategy (*MalVPatch*) to counter the adversarial attacks on malware detection models. The *MalVPatch* defense achieves higher detection accuracy along with a drastic improvement in the adversarial robustness of malware detection models. Finally, we conclude that investigating the adversarial robustness of models is necessary before their real-world deployment and helps achieve adversarial superiority in android malware detection.

“You are what the permissions told me! Android malware detection based on hybrid tactics,”

Recent years have witnessed a significant increase in the use of Android devices in many aspects of our life. However, users can download Android apps from third-party channels, which provides numerous opportunities for malware. Attackers utilize unsolicited permissions to gain access to the sensitive private intelligence of users. Since signature-based antivirus solutions no longer meet practical needs, efficient and adaptable solutions are desperately needed, especially in new variants. As a remedy, we propose a hybrid Android malware detection approach that combines dynamic and static tactics. We firstly adopt static analysis inferring different permission usage patterns between malware and benign apps based on

the machine-learning-based method. To classify the suspicious apps further, we extract the object reference relationships from the memory heap to construct a dynamic feature base. We then present an improved state-based algorithm based on DAMBA. Experimental results on a real-world dataset of 21,708 apps show that our approach outperforms the well-known detector with 97.5% F1-measure. Besides, our system is demonstrated to resist permission abuse behaviors and obfuscation techniques.

“Metaheuristics with deep learning model for cybersecurity and Android malware detection and classification,”

Since the development of information systems during the last decade, cybersecurity has become a critical concern for many groups, organizations, and institutions. Malware applications are among the commonly used tools and tactics for perpetrating a cyberattack on Android devices, and it is becoming a challenging task to develop novel ways of identifying them. There are various malware detection models available to strengthen the Android operating system against such attacks. These malware detectors categorize the target applications based on the patterns that exist in the features present in the Android applications. As the analytics data continue to grow, they negatively affect the Android defense mechanisms. Since large numbers of unwanted features create a performance bottleneck for the detection mechanism, feature selection techniques are found to be beneficial. This work presents a Rock Hyrax Swarm Optimization with deep learning-based Android malware detection

(RHSODL-AMD) model. The technique presented includes finding the Application Programming Interfaces (API) calls and the most significant permissions, which results in effective discrimination between the good ware and malware applications. Therefore, an RHSO based feature subset selection (RHSO-FS) technique is derived to improve the classification results. In addition, the Adamax optimizer with attention recurrent autoencoder (ARAE) model is employed for Android malware detection. The experimental validation of the RHSODL-AMD technique on the Andro-AutoPsy dataset exhibits its promising performance, with a maximum accuracy of 99.05%.

“A method for automatic Android malware detection based on static analysis and deep learning,”

The computers nowadays are being replaced by the smartphones for the most of the internet users around the world, and Android is getting the most of the smartphone systems' market. This rise of the usage of smartphones generally, and the Android system specifically, leads to a strong need to effectively secure Android, as the malware developers are targeting it with sophisticated and obfuscated malware applications. Consequently, a lot of studies were performed to propose a robust method to detect and classify android malicious software (malware). Some of them were effective, some were not; with accuracy below 90%, and some of them are being outdated; using datasets that became old containing applications for old versions of Android that are rarely used today. In this paper, a new method is proposed by using

static analysis and gathering as most useful features of android applications as possible, along with two new proposed features, and then passing them to a functional API deep learning model we made. This method was implemented on a new and classified android application dataset, using 14079 malware and benign samples in total, with malware samples classified into four malware classes. Two major experiments with this dataset were implemented, one for malware detection with the dataset samples categorized into two classes as just malware and benign, the second one was made for malware detection and classification, using all the five classes of the dataset. As a result, our model overcomes the related works when using just two classes with F1-score of 99.5%. Also, high malware detection and classification performance was obtained by using the five classes, with F1-score of 97%.

3. EXISTING SYSTEM

Shaukat et al. [11] devise a new DL-related method for detecting malware. It delivered superior outcomes to classical methods by merging dynamic and static analysis benefits. Firstly, it visualizes a portable executable (PE) file as coloured images. Secondly, it extracted deep features from colour images utilizing fine-tuned DL method. Thirdly, it finds malware related to the deep features of SVM. Geremias et al. [12] presented a method using image-based DL called novel multi-view Android malware identification, applied threefold. Firstly, as per the many feature sets in multi-view settings, apps were assessed, thereby raising the data presented for the classification. Secondly, the derived feature

set is transformed into image formats while preserving the essential elements of data distribution, keeping the data for the classifier task. Thirdly, built images are collectively depicted in one shot, all in a predefined image channel, allowing the implementation of DL structure.

Kim et al. [13] modelled a malware detection system called MAPAS that attains higher precision and adaptable use of computational resources. MAPAS examined the performances of malicious apps based on API call graphs of them through CNN. However, the presented MAPAS technique does not utilize a classifier method produced by CNN, it uses CNN to find typical attributes of the API call graph of malware. Fallah and Bidgoly [14] developed a technique related to LSTM for detecting malware-having the capability of differentiating benign and malware samples and identifying and detecting unseen and new types of malware. In this study, the author has executed many studies to show the abilities of the presented technique, including new malware family detection, malware identification, malware family identification, as well as assessing the minimal time needed to find malware.

Sihag et al. [15] introduced DL-based Android malware identification with the use of DYNAMIC features (De-LADY), a resilient obfuscation method. It has used behavioural features from dynamic analysis of an application performed in the emulated setting. Wang et al. [16] present a hybrid method related to DAE and CNN. Firstly, to

enhance the precision of malware detection, the author reconstructed the high-dimensional feature of apps and used many CNN to find Android malware. Secondly, to diminish the training period, the author used DAE as a pre-training approach for CNN. With the consolidation, DAE and CNN method (DAE-CNN) can study flexible patterns quickly.

Yadav et al. [17] presented a performance comparison of 26 existing pretrained CNN methods in Android malware detection. Depending on the outcomes, to find Android malware, an EfficientNet-B4 CNN-based approach was devised with the use of an image-based malware representation of the Android DEX file. From the malware images, EfficientNet-B4 extracted relevant attributes. Masum and Shahriar [18] devised a DL structure named Droid-NNet, for classifying malware. But this technique Droid-NNet, is a deep learner that surpasses existing cutting-edge ML approaches. Idrees et al. [19] examine PIndroid – a new Permission and Intents-based structure to detect Android malware applications. As we know, PIndroid is the primary solution, which utilizes a group of permissions and purposes supplemented with Ensemble approaches for correct malware detection. In [20], the authors establish that once the concept drift was discussed, permissions create long-lasting and effectual malware detection methods. Taha and Barukab [21] introduce a mechanism for Android malware classification utilizing optimizer ensemble learning depending on GA. The GA was utilized for optimizing the parameter settings from the RF technique for obtaining

the maximum Android malware classifier accuracy. Sabanci et al. [22] intended to categorize pepper seeds belonging to distinct cultivars with CNN techniques. Two methods are presented for classification. Initially, the CNN approaches (ResNet50 and ResNet18) are trained for pepper seeds. Secondary, diverse in the first, the features of pre-training CNN approaches are fused, and feature selection has been executed to the fused features. In [23], the authors examine recent algorithms utilized for Android Malware Detection. As a result, an outline of the Android system exposed the underlying processes and the problems facing its security structure.

Disadvantages

- The complexity of data: Most of the existing machine learning models must be able to accurately interpret large and complex datasets to detect Android Malware Detection.
- Data availability: Most machine learning models require large amounts of data to create accurate predictions. If data is unavailable in sufficient quantities, then model accuracy may suffer.
- Incorrect labeling: The existing machine learning models are only as accurate as the data trained using the input dataset. If the data has been incorrectly labeled, the model cannot make accurate predictions.

4. PROPOSED SYSTEM

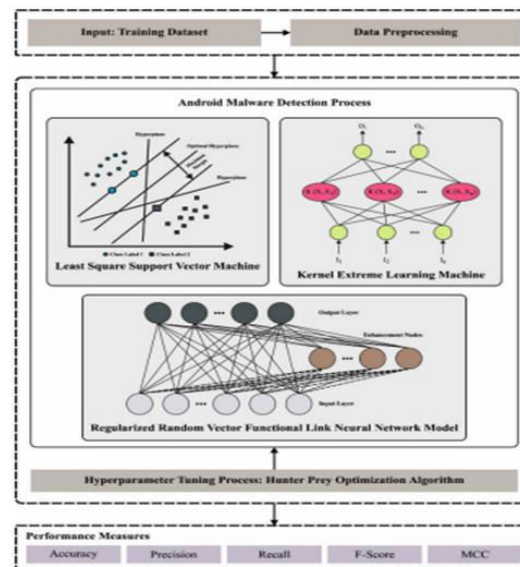

This paper presents an Automated Android Malware Detection using Optimal Ensemble Learning Approach for Cybersecurity (AAMD-OELAC) technique. The AAMD-OELAC technique performs data preprocessing at the preliminary stage. For

the Android malware detection process, the AAMD-OELAC technique follows an ensemble learning process using three ML models, namely Least Square Support Vector Machine (LS-SVM), kernel extreme learning machine (KELM), and Regularized random vector functional link neural network (RRVFLN). Finally, the hunter-prey optimization (HPO) algorithm is exploited for the optimal parameter tuning of the three DL models, and it helps accomplish improved malware detection results. To indicate the supremacy of the AAMD-OELAC approach, a comprehensive experimental analysis is carried out.

Advantages

- An intelligent AAMD-OELAC technique comprising data preprocessing, ensemble learning, and HPO-based hyperparameter tuning is presented for Android malware detection. To the best of our knowledge, the AAMD-OELAC technique never existed in the literature.
- Perform ensemble learning-based classification process comprising LS-SVM, KELM, and RRVFLN models for Android malware detection.
- The combination of the HPO algorithm and ensemble learning process improves the detection accuracy of Android malware. By utilizing multiple classifiers and optimization strategies, the model can effectively identify malicious patterns and behaviours in Android applications.

5. SYSTEM ARCHITECTURE

6. IMPLEMENTATION

Modules

Service Provider

In this module, the Service Provider has to login by using valid user name and password. After login successful he can do some operations such as Train and Test Data Sets, View Trained and Tested Accuracy in Bar Chart, View Trained and Tested Accuracy Results, View Predicted Android Malware Detection Details, Find Predicted Android Malware Detection Ratio, Download Predicted Datasets, View Android Malware Predicted Ratio Results, View All Remote Users.

View and Authorize Users

In this module, the admin can view the list of users who all registered. In this, the admin can view the user's details such as, user name, email, address and admin authorizes the users.

Remote User

In this module, there are n numbers of users are present. User should register before doing any operations. Once user registers, their details will be stored to the database. After registration successful, he has to login by using authorized user name and password. Once Login is successful user will do some operations like REGISTER AND LOGIN, PREDICT ANDROID MALWARE TYPE, VIEW YOUR PROFILE.

7. ALGORITHMS

Naïve Bayes

The naive bayes approach is a supervised learning method which is based on a simplistic hypothesis: it assumes that the presence (or absence) of a particular feature of a class is unrelated to the presence (or absence) of any other feature .

Yet, despite this, it appears robust and efficient. Its performance is comparable to other supervised learning techniques. Various reasons have been advanced in the literature. In this tutorial, we highlight an explanation based on the representation bias. The naive bayes classifier is a linear classifier, as well as linear discriminant analysis, logistic regression or linear SVM (support vector machine). The difference lies on the method of estimating the parameters of the classifier (the learning bias).

While the Naive Bayes classifier is widely used in the research world, it is not widespread among practitioners which want to obtain usable results. On the one hand, the

researchers found especially it is very easy to program and implement it, its parameters are easy to estimate, learning is very fast even on very large databases, its accuracy is reasonably good in comparison to the other approaches. On the other hand, the final users do not obtain a model easy to interpret and deploy, they does not understand the interest of such a technique.

Thus, we introduce in a new presentation of the results of the learning process. The classifier is easier to understand, and its deployment is also made easier. In the first part of this tutorial, we present some theoretical aspects of the naive bayes classifier. Then, we implement the approach on a dataset with Tanagra. We compare the obtained results (the parameters of the model) to those obtained with other linear approaches such as the logistic regression, the linear discriminant analysis and the linear SVM. We note that the results are highly consistent. This largely explains the good performance of the method in comparison to others. In the second part, we use various tools on the same dataset (**Weka 3.6.0**, **R 2.9.2**, **Knime 2.1.1**, **Orange 2.0b** and **RapidMiner 4.6.0**). We try above all to understand the obtained results.

Logistic regression Classifiers

Logistic regression analysis studies the association between a categorical dependent variable and a set of independent (explanatory) variables. The name logistic regression is used when the dependent variable has only two values, such as 0 and 1 or Yes and No. The name multinomial

logistic regression is usually reserved for the case when the dependent variable has three or more unique values, such as Married, Single, Divorced, or Widowed. Although the type of data used for the dependent variable is different from that of multiple regression, the practical use of the procedure is similar.

Logistic regression competes with discriminant analysis as a method for analyzing categorical-response variables. Many statisticians feel that logistic regression is more versatile and better suited for modeling most situations than is discriminant analysis. This is because logistic regression does not assume that the independent variables are normally distributed, as discriminant analysis does.

This program computes binary logistic regression and multinomial logistic regression on both numeric and categorical independent variables. It reports on the regression equation as well as the goodness of fit, odds ratios, confidence limits, likelihood, and deviance. It performs a comprehensive residual analysis including diagnostic residual reports and plots. It can perform an independent variable subset selection search, looking for the best regression model with the fewest independent variables. It provides confidence intervals on predicted values and provides ROC curves to help determine the best cutoff point for classification. It allows you to validate your results by automatically classifying rows that are not used during the analysis.

Decision tree classifiers

Decision tree classifiers are used successfully in many diverse areas. Their most important feature is the capability of capturing descriptive decision making knowledge from the supplied data. Decision tree can be generated from training sets. The procedure for such generation based on the set of objects (S), each belonging to one of the classes C_1, C_2, \dots, C_k is as follows:

Step 1. If all the objects in S belong to the same class, for example C_i , the decision tree for S consists of a leaf labeled with this class

Step 2. Otherwise, let T be some test with possible outcomes O_1, O_2, \dots, O_n . Each object in S has one outcome for T so the test partitions S into subsets S_1, S_2, \dots, S_n where each object in S_i has outcome O_i for T. T becomes the root of the decision tree and for each outcome O_i we build a subsidiary decision tree by invoking the same procedure recursively on the set S_i .

8. CONCLUSION AND FUTURE ENHANCEMENT

We have designed the AAMD-OELAC approach in this work to identify Android malware accurately and automatically. The goal of the AAMD-OELAC method was to automatically identify and categorise Android malware. The AAMD-OELAC approach uses ensemble classification, data preprocessing, and HPO-based parameter adjustment to accomplish this. The AAMD-OELAC approach uses three machine learning models—LS-SVM, KELM, and RRVFLN—as part of an ensemble learning

process for Android malware detection. Lastly, the HPO technique is used to optimise the three DL models' parameter tuning, which leads to better malware detection outcomes. A comprehensive experimental investigation is carried out to demonstrate the superiority of the AAMD-OELAC approach. The simulation results demonstrated the AAMDOELAC technique's superiority over other methods currently in use.

In order to improve the detection of complex malware, future research might concentrate on creating increasingly sophisticated methods for capturing and analysing fine-grained behaviours. Future research might also examine privacy-preserving strategies like federated learning or safe multi-party computing, which allow for cooperative malware detection without jeopardising user privacy.
